Abstract

Extended Producer Responsibility (EPR) is an environmental policy instrument that makes producers responsible for managing the post-consumer stage of their products, including collection, recycling, recovery, and environmentally sound disposal. The policy aims to internalize environmental externalities, reduce the burden on municipal waste-management systems, encourage eco-friendly product design, and promote a circular economy. EPR has become increasingly important in addressing plastic pollution, electronic waste, packaging waste, batteries, and other discarded products. This paper examines the efficiency of EPR as an economic and environmental policy instrument, focusing on its theoretical foundations, implementation mechanisms, institutional challenges, and measurable outcomes. It adopts a descriptive and analytical methodology based on secondary information from government regulations, international organizations, and academic literature. The analysis evaluates EPR in terms of environmental effectiveness, economic efficiency, producer accountability, recycling performance, and administrative feasibility. It finds that EPR can improve waste recovery and shift end-of-life costs from the public sector to producers and consumers, provided that collection infrastructure, monitoring systems, transparent reporting, and effective enforcement are in place. However, weak compliance, inadequate recycling facilities, unreliable waste data, and excessive dependence on certificate-based compliance can undermine its effectiveness. The paper recommends strengthening regulatory oversight, integrating informal waste workers, improving traceability, promoting eco-design, and linking producer obligations to verifiable environmental outcomes. It concludes that EPR is most effective when implemented as part of a comprehensive circular-economy strategy rather than as an isolated waste-management regulation.

Keywords: *Extended Producer Responsibility; circular economy; waste management; recycling efficiency; environmental policy; producer accountability.*

Introduction

Environmental degradation and the increasing generation of solid waste have become major challenges for modern economies. Rapid industrialization, urbanization, rising consumption, technological change, and the expansion of packaged goods have increased the volume and complexity of waste generated by households, businesses, and industries. Conventional waste-management systems frequently place a substantial financial and administrative burden on local governments, while the environmental costs of discarded products are not always reflected in their market prices. Extended Producer Responsibility is designed to address this problem by extending a producer's responsibility beyond the manufacturing and sale of a product to its post-consumer management. Producers may be required to finance, organize, or demonstrate the collection, recycling, recovery, and environmentally sound disposal of products and packaging after use. The precise obligations vary according to the product category and national regulatory framework. The economic rationale for EPR is based on the principle that those who introduce products

[1] *How to cite the article:* Krishnaveni M (March 2026); The Efficiency of Extended Product Responsibility (EPR); *International Journal of Transformations in Business Management,* Vol 16, Issue 1, 158-169, DOI: http://doi.org/10.37648/ijtbm.v16i01.011

into the market should bear an appropriate share of the costs associated with their end-of-life environmental impacts. By assigning these costs to producers, EPR seeks to reduce the burden on public authorities and encourage businesses to redesign products for durability, repairability, reuse, and recycling. The efficiency of EPR, however, cannot be assessed simply by examining whether producers meet their legal obligations. A system may achieve formal compliance without producing equivalent improvements in actual recycling, waste reduction, or environmental quality. Therefore, its performance must be evaluated using measurable indicators such as collection rates, verified recycling rates, costs per tonne recovered, reductions in landfill disposal, compliance levels, and improvements in product design.

Statement of the problem

Although EPR frameworks have expanded internationally, their practical effectiveness varies significantly across jurisdictions and product categories. Regulatory complexity, limited recycling infrastructure, inaccurate reporting, insufficient enforcement, and the exclusion of informal waste collectors can weaken their results. A key policy question is whether EPR generates genuine environmental improvements at a reasonable economic and administrative cost.

Objectives of the study

1. To explain the economic and environmental foundations of Extended Producer Responsibility.
2. To examine the efficiency of EPR in waste collection, recycling, and resource recovery.
3. To analyse the institutional and economic challenges affecting EPR implementation.
4. To assess the relevance of EPR within India's waste-management and circular-economy policies.
5. To suggest measures for improving the effectiveness, transparency, and accountability of EPR systems.

Research questions

- Does EPR improve collection, recycling, and environmentally sound waste management?
- How does EPR influence producers' costs, product design, and environmental responsibility?
- What institutional and market failures limit its efficiency?
- Which policy reforms can strengthen EPR implementation in India?

Review of Literature: The literature on EPR examines its environmental benefits, economic implications, institutional arrangements, and contribution to sustainable production and consumption.

OECD (2016): EPR and efficient waste management: The Organisation for Economic Co-operation and Development (OECD) reviewed the design and implementation of EPR systems in its report Extended Producer Responsibility: Updated Guidance for Efficient Waste Management. The report examines governance, competition, environmentally responsible product design, and the role of the informal sector. It emphasizes that EPR outcomes depend on policy design and institutional capacity rather than the mere existence of producer obligations.

OECD (2024): Basic facts and key principles: The OECD's 2024 policy paper presents EPR as a lifecycle-based approach that extends producer responsibility to the post-consumer stage. It identifies the importance of clear responsibilities, appropriate financial arrangements, and effective governance. The publication provides a framework for understanding EPR across sectors such as plastics, electronic equipment, and textiles.

Colelli et al. (2022): Efficiency of packaging EPR systems: Colelli and colleagues examined more than 25 national packaging-waste schemes and 21 Producer Responsibility Organizations (PROs) in Europe. Their study found that higher recycling rates do not necessarily require higher costs. It also identified an association between better recycling outcomes and systems in which local authorities retain a role in collection and sorting. These findings demonstrate the importance of institutional coordination and cost-efficient operational arrangements.

Ahlers et al. (2021): Comparative assessment of EPR schemes: Ahlers and colleagues compared selected European EPR schemes covering waste electrical and electronic equipment, packaging, and batteries. Their analysis highlighted substantial variation in performance across jurisdictions. Differences in legislation, collection systems, financing arrangements, and compliance procedures affect the efficiency of individual schemes. The study supports the need for context-specific institutional design and comparable performance indicators.

Global E-waste Monitor (2024): The Global E-waste Monitor 2024, published by the United Nations Institute for Training and Research and the International Telecommunication Union, reported that the world generated approximately 62 million tonnes of electronic waste in 2022. Only 22.3% was documented as formally collected and recycled in an environmentally sound manner. This gap highlights the importance of effective collection systems, producer accountability, and reliable recycling infrastructure. However, the figure describes global e-waste management and should not be interpreted as a direct estimate of EPR's causal impact.

Research gap

Existing literature provides substantial evidence on the institutional design and recycling performance of EPR schemes. However, three issues require further attention:

1. The distinction between administrative compliance and actual environmental outcomes.
2. The measurement of economic efficiency alongside collection and recycling performance.
3. The implementation challenges faced by developing economies, particularly in integrating informal waste workers and establishing reliable waste-tracking systems.

This paper addresses these issues through an integrated economic and environmental assessment, with particular attention to India's policy framework.

Conceptual and Theoretical Framework

Meaning of Extended Producer Responsibility: Extended Producer Responsibility is a policy instrument under which producers are assigned responsibility for managing products at the end of their useful lives. Depending on the regulatory framework, the responsibility may be financial, operational, or both.

EPR commonly applies to:

- Plastic packaging and other packaging materials.
- Electrical and electronic equipment.
- Batteries and accumulators.
- End-of-life vehicles and tyres.
- Other regulated product categories, depending on national legislation.

Producer Responsibility Organizations may coordinate the collection, financing, and recycling activities of multiple producers. Nevertheless, outsourcing operational functions does not necessarily remove the producer's underlying legal obligations.

Polluter-pays principle

The polluter-pays principle requires environmental costs to be borne by those responsible for generating pollution, rather than being transferred entirely to society.

Without EPR, municipalities and taxpayers may bear a substantial proportion of the cost of collecting and disposing of discarded products. EPR attempts to redistribute these costs towards producers and, depending on market conditions, consumers.

The intended result is better alignment between private production decisions and social environmental costs.

Environmental externalities

An environmental externality occurs when the production or consumption of a good imposes costs on third parties that are not fully reflected in its market price.

For example, plastic packaging discarded into waterways can impose cleanup costs, damage ecosystems, and contribute to pollution. If these costs are excluded from the producer's decision-making process, the market may generate excessive quantities of environmentally harmful packaging. EPR can reduce this market failure by introducing fees, collection obligations, recycling targets, or other requirements that incorporate end-of-life costs into production and consumption decisions.

Economic efficiency of EPR

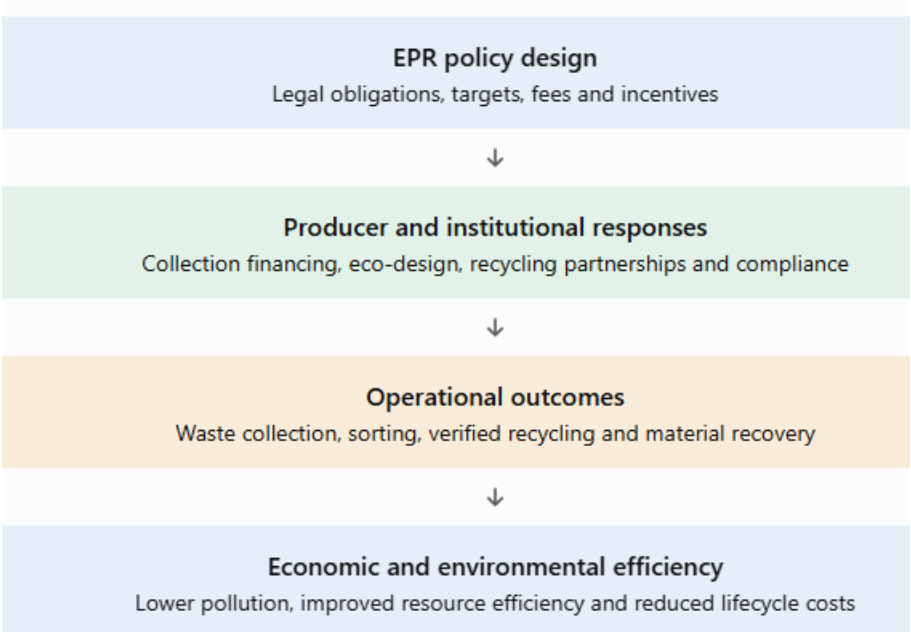
The economic efficiency of EPR can be evaluated using the following conceptual expression:

Net Social Benefit = Environmental Benefit + Resource Recovery Benefits

Total system costs include collection, transportation, sorting, recycling, administration, monitoring, and compliance expenses. Environmental benefits may include reduced pollution, lower landfill use, and avoided extraction of virgin materials.

A system is economically efficient when the net social benefits of its activities are positive and the desired environmental outcomes are achieved at a reasonable cost.

Conceptual framework



Research Methodology

Research design

The study adopts a descriptive and analytical research design. It examines EPR as an environmental economic instrument by combining theoretical analysis, a review of published empirical studies, and policy analysis.

Sources of data

The analysis draws on secondary sources, including:

- OECD publications on EPR and environmental policy.
- Government of India regulations and Central Pollution Control Board (CPCB) materials.
- International reports on electronic waste.
- Peer-reviewed research on the efficiency of packaging EPR systems.
- Published comparative studies of EPR implementation.

Analytical approach

The study evaluates EPR along five dimensions:

1. Environmental effectiveness: Whether waste collection, recycling, and safe disposal improve.
2. Economic efficiency: Whether environmental outcomes are achieved at reasonable total cost.
3. Producer accountability: Whether producers meet their legal and financial responsibilities.
4. Institutional effectiveness: Whether regulators, local governments, recyclers, and producer organizations coordinate effectively.
5. Circular-economy performance: Whether EPR promotes reuse, repair, recycled-material use, and waste prevention.

Limitations

This is a secondary-data study rather than an original econometric investigation. The international and Indian evidence discussed below is drawn from different years, jurisdictions, and product categories. The results therefore support a comparative assessment but do not establish a single causal estimate of EPR's overall impact. A stronger causal evaluation would require comparable time-series or firm-level data, a defined counterfactual, and consistent cost and recycling measures.

Analysis and Discussion

1. **Environmental effectiveness:** The first test of EPR is whether it improves the actual management of discarded products. An effective system should increase the quantity of waste collected through authorized channels, improve sorting and recycling, reduce uncontrolled disposal, and ensure environmentally sound treatment of hazardous waste. The global e-waste evidence demonstrates the scale of the challenge. Of the 62 million tonnes generated in 2022, only 22.3% was documented as formally collected and recycled in an environmentally sound manner. The remaining share was not documented as meeting that standard; it should not automatically be classified as entirely unrecycled, because some material may enter undocumented or other recovery routes. This evidence suggests that formal policies alone cannot guarantee environmental effectiveness. Collection facilities, consumer participation, repair and reuse networks, safe recycling capacity, and reliable reporting are equally important.
2. **Economic efficiency and cost-effectiveness:** EPR transfers some end-of-life management costs from general public budgets to producers, producer organizations, and potentially consumers through product prices. This can improve the allocation of costs when producer obligations reflect the environmental impacts of products. However, cost shifting is not the same as cost reduction. EPR fees, administrative expenses, transportation, and compliance requirements can increase private costs. The broader economic benefit depends on whether these costs are offset by lower pollution, improved resource recovery, reduced public expenditure, and the value of recovered materials. The European packaging evidence reported by Colelli et al. (2022) is particularly relevant: systems achieving higher recycling rates did not necessarily incur higher costs. The study also identified the importance of local-authority involvement in collection and sorting.

Therefore, the efficiency of EPR should be measured using both the quantity and quality of recycling and the total cost of achieving those outcomes.

3. **Producer accountability and eco-design:** A major objective of EPR is to encourage producers to account for end-of-life costs when designing products.

   Producers may respond by:

   - Reducing unnecessary packaging.
   - Increasing the use of recyclable materials.
   - Designing products for easier repair and disassembly.
   - Increasing recycled content.
   - Reducing hazardous substances.
   - Extending product life and improving reuse options.

   Nevertheless, these changes are not automatic. Where compliance is based mainly on meeting recycling targets or purchasing compliance certificates, producers may have limited incentives to reduce waste at the design stage. A more effective approach is to vary EPR fees according to product characteristics, such as recyclability, durability, repairability, and the use of recycled materials. Such differentiated fees can provide a stronger price signal for environmentally preferable design.

4. **Institutional and governance efficiency:** EPR systems involve producers, regulators, local governments, waste collectors, recycling facilities, consumers, and producer responsibility organizations. Poor coordination can lead to duplicated expenditure, gaps in collection, weak enforcement, and unreliable performance reporting.

   An effective institutional framework requires:

   1. Clear allocation of responsibilities.
   2. Transparent producer registration.
   3. Verification of recycling quantities.
   4. Independent audits of recycling facilities.
   5. Penalties proportionate to non-compliance.
   6. Coordination between national and state authorities.
   7. Public reporting of environmental outcomes.

   Digital reporting systems can help track material flows, but digital records must be checked against physical quantities processed by authorized facilities. Otherwise, a technically sophisticated portal may record administrative compliance without establishing equivalent environmental performance.

5. **EPR and the informal waste sector:** In many developing economies, informal waste collectors and scrap dealers play a significant role in recovering valuable materials. They may provide collection services at low cost while operating outside formal reporting and occupational-safety systems. Excluding these workers can reduce the quantity of waste recovered and weaken existing collection networks. Conversely, integrating them into formal systems can improve traceability, occupational safety, access to stable incomes, and recycling performance. Policy measures should include worker registration where appropriate, training, protective equipment, fair payment arrangements, access to collection contracts, and links with authorized recycling facilities.

6. **India's EPR policy framework:** India has introduced EPR requirements for several waste streams. For plastic packaging, the Ministry of Environment, Forest and Climate Change notified EPR guidelines through the Plastic Waste Management Amendment Rules in February 2022. The CPCB subsequently provided a centralized portal for registration and compliance-related processes involving producers, importers, brand owners, and plastic waste processors. The policy framework creates an institutional basis for assigning responsibility to market participants and monitoring their obligations. Its effectiveness, however, depends on the accuracy of waste data, verification of recycling claims, enforcement against non-compliant entities, and the availability of adequate processing facilities.

India's large informal recycling sector also means that implementation must account for existing collection and recovery networks. Formalization should improve environmental standards and worker protection without unnecessarily displacing livelihoods.

The following table summarizes the main dimensions of EPR performance.

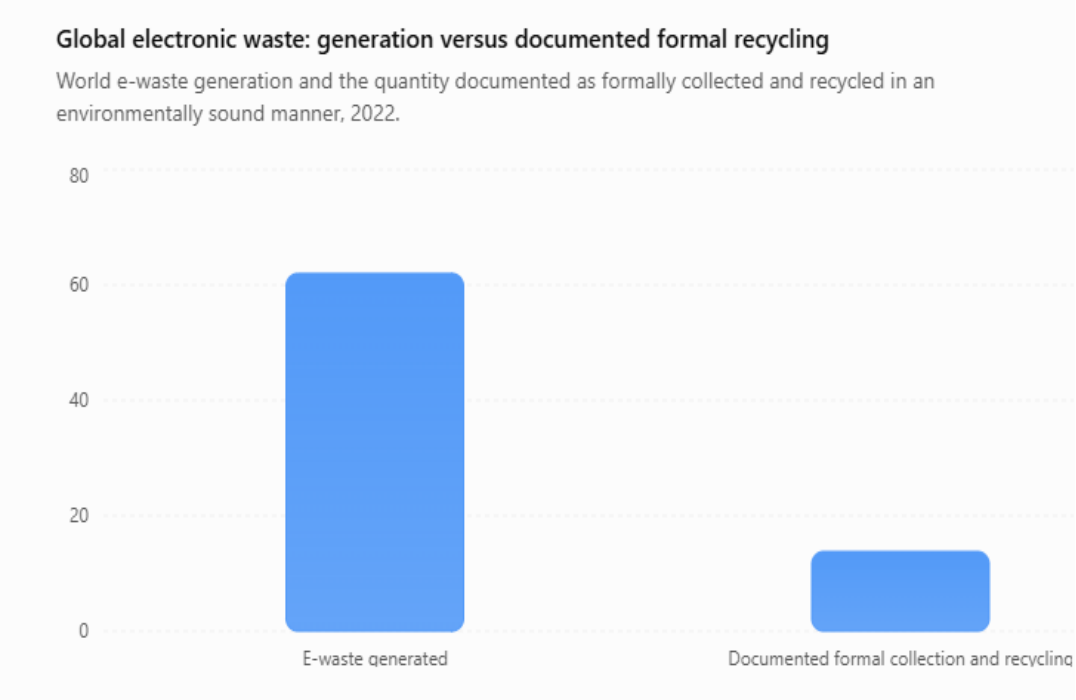
Dimension	Potential benefit	Main efficiency risk
Waste collection	Higher recovery and less uncontrolled disposal	Inadequate collection infrastructure
Recycling	Greater material recovery	False, duplicate or unverifiable claims
Producer incentives	Eco-design and reduced material use	Fees too weak to change design
Public finance	Reduced municipal financial burden	Public costs remain where systems are incomplete
Governance	Better accountability and traceability	Weak audits and fragmented responsibilities
Employment	Formal opportunities for waste workers	Exclusion of informal collectors
Circular economy	Greater reuse and recycled-material use	Excessive focus on recycling instead of prevention

Statistical Analysis and Empirical Evidence

This section presents published empirical evidence relevant to the efficiency of EPR. The figures are observations from identified sources, not original survey results generated by the author.

Global electronic-waste generation and formal recycling

The Global E-waste Monitor 2024 provides a useful indicator of the gap between waste generation and documented formal recycling.



The reported figures imply the following:

Documented formal recycling rate $= \frac{13.8}{62} \boldsymbol{x\ 100 = 22.3\%}$

The difference between total generation and documented formal collection and recycling was approximately 48.2 million tonnes. This is a gap in documented formal management, not a direct measurement of waste that was never recycled through any channel.

The report also found that global e-waste generation had increased faster than documented formal collection and recycling. This indicates that formal recovery systems have struggled to keep pace with the growing volume of discarded electronic products.

Interpretation: EPR needs to be assessed by the quantity of waste actually collected and safely processed, rather than by the number of registered producers or certificates issued.

Evidence from European packaging-waste schemes

Colelli et al. (2022) assessed more than 25 national packaging-waste schemes and 21 Producer Responsibility Organizations.

Their findings provide three important insights:

1. Higher recycling rates do not necessarily entail higher costs.
2. Some institutional arrangements are more effective at converting producer fees into recycling outcomes.
3. Systems retaining a meaningful role for local authorities in collection and sorting performed better on recycling rates in the study.

These results challenge the assumption that the most competitive or lowest-cost administrative structure will always be the most environmentally efficient. The objective should be to minimize the cost of achieving a specified environmental outcome, rather than minimize expenditure irrespective of performance.

India: policy and implementation indicators

India's plastic-packaging EPR framework establishes registration and compliance procedures for producers, importers, brand owners, and plastic waste processors. The CPCB's centralized portal supports these processes. The existence of this framework demonstrates regulatory progress, but registration and reporting alone are insufficient to establish overall efficiency. A rigorous assessment requires data on actual quantities placed on the market, waste collected, recycling yields, disposal routes, verified recycled content, compliance costs, and enforcement actions.

For a quantitative Indian assessment, the following indicators should be compiled from CPCB and relevant state pollution-control board records.

Indicator	Measurement	Purpose
EPR compliance rate	Compliant obligated entities ÷ total obligated entities × 100	Measures regulatory compliance
Collection rate	Waste collected ÷ waste generated × 100	Measures collection performance
Verified recycling rate	Waste actually recycled ÷ waste generated × 100	Measures recycling effectiveness
Cost per tonne recycled	Total system expenditure ÷ tonnes actually recycled	Measures cost-efficiency
Recovery yield	Usable secondary material recovered ÷ waste processed × 100	Measures material recovery
Municipal cost reduction	Baseline municipal cost minus current cost, adjusted for scope	Measures public-finance impact
Eco-design performance	Change in packaging intensity, recyclability or recycled content	Measures preventive impact

These indicators should be reported separately for plastic packaging, electronic waste, batteries, and other regulated streams. They should not be combined without adjustments for differences in waste composition, technology, and treatment costs.

Measuring cost-efficiency

A simple operational indicator is:

$$\mathrm{CE} = \frac{\text{Verified tonnes recycled}}{\text{Total system cost}}$$

A higher value indicates that more material is recycled per unit of expenditure. For comparisons across regions or years, costs should be expressed in constant prices and the same definitions of recycling and system expenditure should be used.

A complementary measure is:

$$C_T = \frac{Total\ System\ Cost}{\text{Total system cost}\text{Verified tonnes recycled}}$$

Here, C_T represents the cost per verified tonne recycled. A lower figure is desirable only when recycling quality, environmental safety, and material recovery are comparable.

Overall assessment of efficiency

The reviewed evidence indicates that EPR has a credible economic rationale and can support higher recycling performance. However, its success depends on the institutional arrangements through which producer obligations are converted into physical waste collection, safe treatment, and useful secondary materials.

The available evidence does not justify assigning one universal efficiency percentage to EPR. Performance differs across waste streams, regulatory settings, and measurement methods. A meaningful assessment must distinguish policy adoption, legal compliance, physical recovery, and net social benefits.

Major Findings: The analysis produces the following findings.

1. PR can improve the allocation of environmental costs. By assigning end-of-life obligations to producers, EPR can reduce the extent to which waste-management costs are borne entirely by municipalities and taxpayers. The degree of cost transfer depends on implementation and on how producers pass costs through to consumers.
2. Formal compliance does not guarantee environmental efficiency. Producer registration, financial contributions, and compliance certificates are useful administrative indicators, but they cannot substitute for verified evidence of collection and environmentally sound recycling.
3. Recycling performance depends on institutional coordination. The European packaging evidence indicates that the involvement of local authorities in collection and sorting can be associated with better recycling outcomes. EPR should therefore complement municipal waste-management systems rather than operate independently of them.
4. EPR has potential to encourage eco-design, but incentives matter. Where fees do not adequately reflect recyclability, durability, repairability, and material impacts, producers may prioritize minimum compliance over product redesign.
5. Inadequate infrastructure limits effectiveness. Even well-designed legal obligations may produce weak results where collection networks, authorized treatment facilities, technology, and markets for recovered materials are insufficient.
6. The informal waste sector is economically significant. Policies that integrate informal collectors and scrap dealers can strengthen existing recovery networks while improving traceability, occupational safety, and livelihoods.
7. The expansion of electronic waste makes stronger implementation increasingly important. Global data show that documented formal collection and recycling have not kept pace with e-waste generation, reinforcing the need for improved recovery systems.
8. EPR should be evaluated as a system rather than a standalone regulation. Its effectiveness depends on the interaction of economic incentives, regulatory enforcement, local infrastructure, consumer participation, and demand for recycled materials.

Suggestions and Policy Recommendations

- **Strengthen monitoring and verification:** Regulators should establish reliable systems to verify the movement of waste from collection points to authorized treatment and recycling facilities. Digital tracking should be supported by physical inspections, independent audits, and checks against actual processing capacity.
- **Introduce stronger eco-modulated fees:** EPR fees should reflect differences in the environmental characteristics of products. Products that are difficult to recycle, contain hazardous materials, or use excessive packaging may face higher fees, while products designed for repair, reuse, and high-quality recycling may receive lower fees where justified. This would strengthen the incentive to prevent waste rather than focus exclusively on its disposal after consumption.

- **Improve collection and recycling infrastructure:** Governments should support investment in segregation, collection, sorting, recycling, and safe treatment facilities, particularly in underserved urban and rural areas. Public-private partnerships may be appropriate where they provide transparent contracts and verifiable environmental results.
- **Integrate informal waste workers:** Informal collectors and scrap dealers should be incorporated into authorized collection and recovery networks through training, suitable contractual arrangements, occupational-safety measures, and fair remuneration. Their integration should improve environmental compliance without unnecessarily destroying existing livelihoods.
- **Improve coordination with local governments:** Local authorities should have clearly defined responsibilities in waste collection, sorting, public awareness, and monitoring. Financing arrangements should recognize their actual costs and avoid duplication between municipal services and producer responsibility organizations.
- **Develop performance-based EPR targets:** Targets should be linked to independently verify environmental outcomes, including collection, recycling quality, material recovery, and reductions in uncontrolled disposal. Where appropriate, separate targets should be established for reuse and waste prevention. Performance assessments should also account for contamination, recycling residues, and the environmental quality of the treatment process.
- **Promote consumer awareness:** Public awareness programmes should explain waste segregation, take-back arrangements, repair options, and authorized disposal channels. Retailers and producers can support convenient collection points and take-back services.
- **Improve transparency and public reporting:** Annual reports should disclose the quantities of products placed on the market, waste collected, material recycled, residues disposed of, compliance costs, and penalties imposed for violations. Data should be published in consistent formats to permit comparisons across years and jurisdictions.
- **Strengthen research and independent evaluation:** Universities, research institutions, and environmental agencies should undertake independent assessments of EPR programmes. Such studies should estimate cost per tonne recovered, environmental benefits, producer responses, employment effects, and changes in municipal expenditure. Where sufficient data exist, researchers should use before-and-after comparisons, regional comparisons, and appropriate econometric methods to distinguish EPR's effects from other changes in waste-management policy.
- **Adopt a circular-economy approach:** EPR should be integrated with waste prevention, product-life extension, repair, reuse, recycled-material markets, and sustainable public procurement. Recycling remains important, but it should not become a justification for continued unnecessary production or disposable product design.

Conclusion

Extended Producer Responsibility is an important environmental economic instrument for addressing the growing problem of waste generation and inefficient resource use. By assigning producers responsibility for the post-consumer management of their products, EPR seeks to internalize environmental externalities, improve recycling, reduce the financial burden on public authorities, and promote a circular economy. The analysis demonstrates that the effectiveness of EPR depends not simply on the existence of legislation but on the quality of its implementation. Clear producer obligations, effective monitoring, adequate infrastructure, reliable waste data, and cooperation among producers, local governments, recyclers, and consumers are essential for achieving meaningful results. International evidence indicates that EPR schemes can support improved recycling performance without necessarily increasing costs proportionately. Nevertheless, the substantial gap between global e-waste generation and documented formal recycling demonstrates that the broader waste-management challenge remains unresolved. India's regulatory framework provides a basis for strengthening producer accountability, but its overall efficiency must be assessed using verified physical recovery, cost, compliance, and environmental indicators. The study concludes that EPR is most

effective when it combines the polluter-pays principle with transparent governance, performance-based targets, eco-design incentives, and the integration of informal waste workers. Policymakers should move beyond measuring administrative compliance and focus on demonstrable environmental improvements and net social benefits. Ultimately, EPR should be regarded not merely as a mechanism for financing waste disposal but as a means of transforming production and consumption patterns. Its long-term success depends on whether it encourages producers to prevent waste, consumers to adopt responsible practices, and institutions to recover resources efficiently while protecting the environment.
